

Game Playing

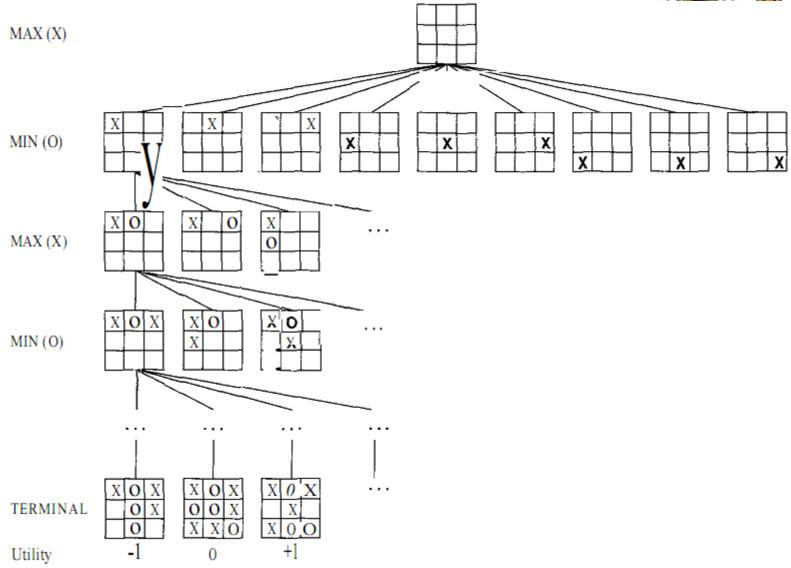

MiniMax Algorithm

A game can be formally defined as a kind of search problem with the following components:

- The initial state, which includes the board position and an indication of whose move it is.
- A set of operators, which define the legal moves that a player can make.
- A terminal test, which determines when the game is over. States where the game has ended are called terminal states.
- A utility function (also called a payoff function), which gives a numeric value for the outcome of a game. In chess, the outcome is a win, loss, or draw, which we can represent by the values +1, −1, or 0. Some games have a wider variety of possible outcomes; for example, the payoffs in backgammon range from +192 to −192.

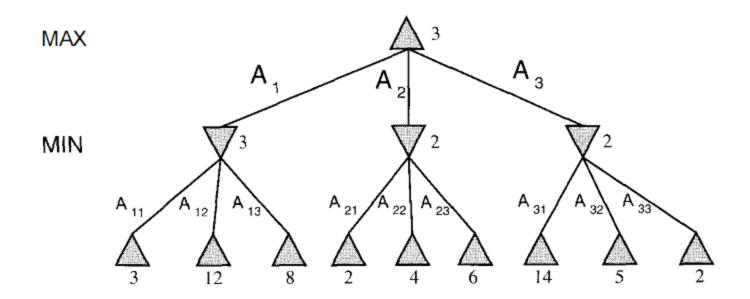

Process of MINIMAX Algorithm

The **minimax** algorithm is designed to determine the optimal strategy for MAX, and thus to decide what the best first move is. The algorithm consists of five steps:

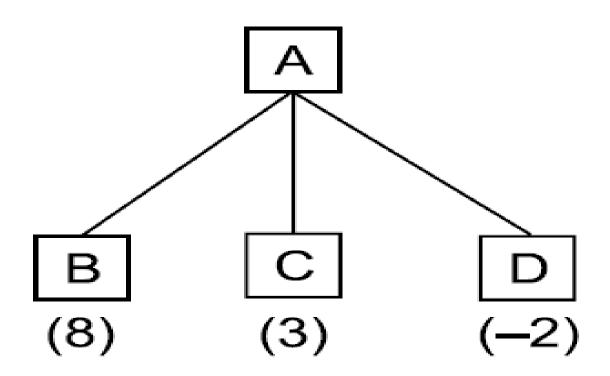

- Generate the whole game tree, all the way down to the terminal states.
- Apply the utility function to each terminal state to get its value.
- Use the utility of the terminal states to determine the utility of the nodes one level higher up in the search tree. Consider the leftmost three leaf nodes in Figure 5.2. In the V node above it, MIN has the option to move, and the best MIN can do is choose A_{11} , which leads to the minimal outcome, 3. Thus, even though the utility function is not immediately applicable to this V node, we can assign it the utility value 3, under the assumption that MIN will do the right thing. By similar reasoning, the other two V nodes are assigned the utility value 2.
- Continue backing up the values from the leaf nodes toward the root, one layer at a time.
- Eventually, the backed-up values reach the top of the tree; at that point, MAX chooses the
 move that leads to the highest value. In the topmost A node of Figure 5.2, MAX has a choice
 of three moves that will lead to states with utility 3, 2, and 2, respectively. Thus, MAX's
 best opening move is A] 1. This is called the mininiax decision, because it maximizes the
 utility under the assumption that the opponent will play perfectly to minimize it.

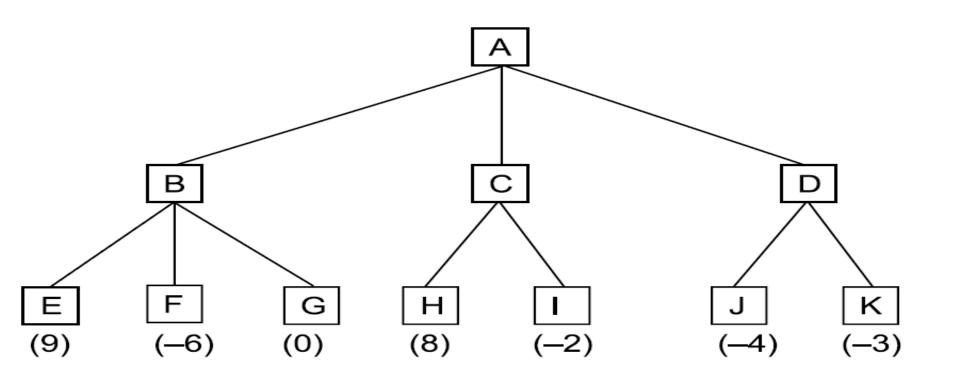

One – Ply Search

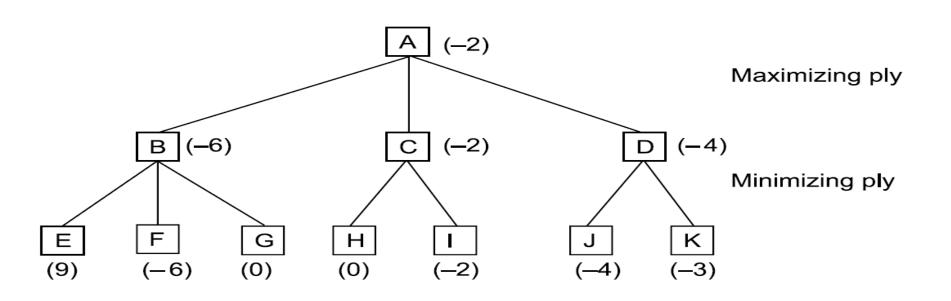

Two - Ply Search

Backing Up the Values of a Two – Ply Search

function MINIMAX-DECISION(game) **returns** an operator

```
for each op in OPERATORS[game] do
   VALUE[op] — MINIMAX-VALUE(APPLY(op, game), game)
end
return the op with the highest VALUE[op]
```

function MINIMAX-VALUE(state, game) returns a utility value

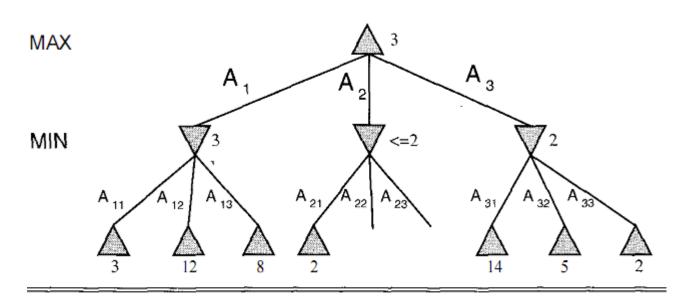

if TERMINAL-TEST[game](state) then UTILITY[game](state) return else if MAX is to move in state then **return** the highest MINIMAX-VALUE of SUCCESSORS(*state*) else **return** the lowest MINIMAX-VALUE of SUCCESSORS(state)

ALPHA-BETAPRUNING

Fortunately, it is possible to compute the correct minimax decision without looking at every node in the search tree. The process of eliminating a branch of the search tree from consideration without examining it is called **pruning** the search tree. The particular technique we will examine is called **alpha-beta pruning.** When applied to a standard minimax tree, it returns the same move

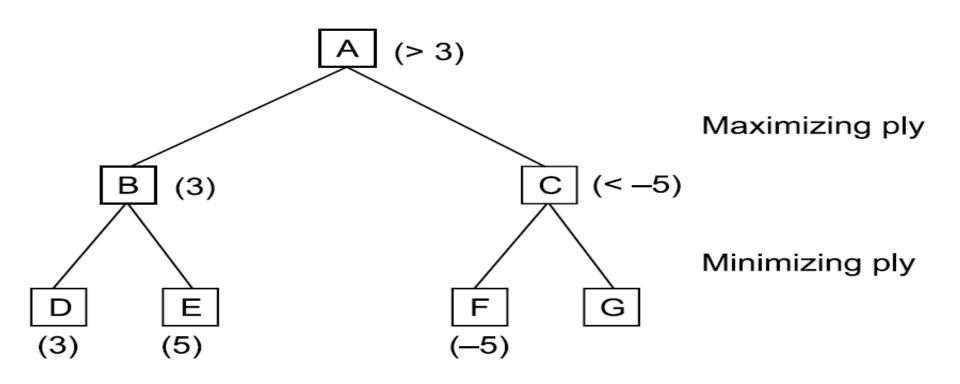

as minimax would, but prunes away branches that cannot possibly influence the final decision.

The two-ply game tree as generated by alpha-beta.

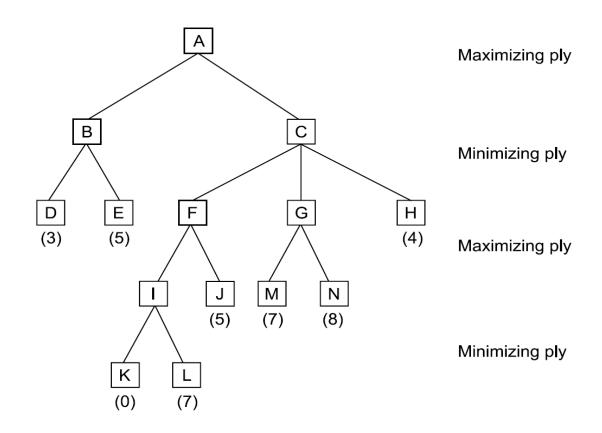

Alpha – Beta Pruning

Alpha and Beta Cutoffs

The general principle is this. Consider a node *n* somewhere in the tree (see Figure 5.7), such that Player has a choice of moving to that node. If Player has a better choice *m* either at the parent node of n, or at any choice point further up, then *n* will never be reached in actual play.

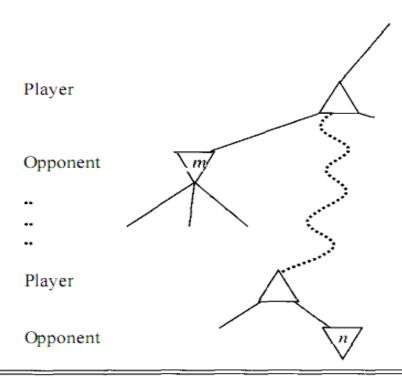

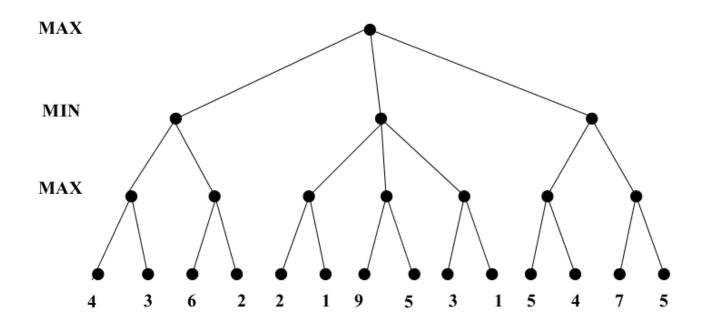

Figure 5.7 Alpha-beta pruning: the general case. If m is better than n for Player, we will never get to n in play.

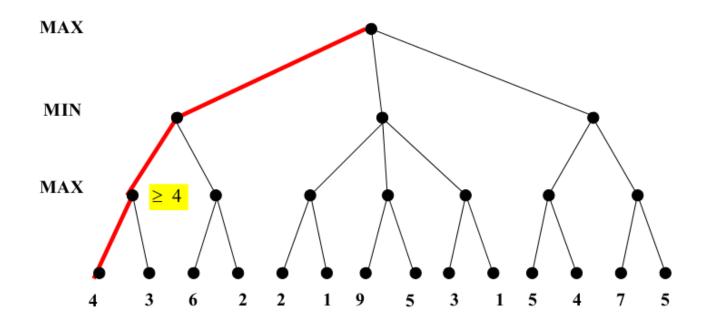

```
function MAX-VALUE(stategame, a, \beta) returns the minimax value of state
  inputs: state, current state in game
          game, game description
          a, the best score for MAX along the path to state
          \beta, the best score for MIN along the path to state
  if CUTOFF-TEST(state) then return EVAL(state)
  for each s in SUCCESSORS(state) do
      a \leftarrow \text{MAX}(\alpha, \text{MIN-VALUE}(s, game, a, \beta))
      if a > ft then return ft
  end
  return a
function MIN-VALUE(state, game, a, ft) returns the minimax value of state
  if CUTOFF-TEST(state) then return EVAL(state)
  for each s in SUCCESSORS(state) do
     ft - MIN(ft, MAX-VALUE(s, game, a, \beta))
      if ft < a then return a
  end
  return ft
```

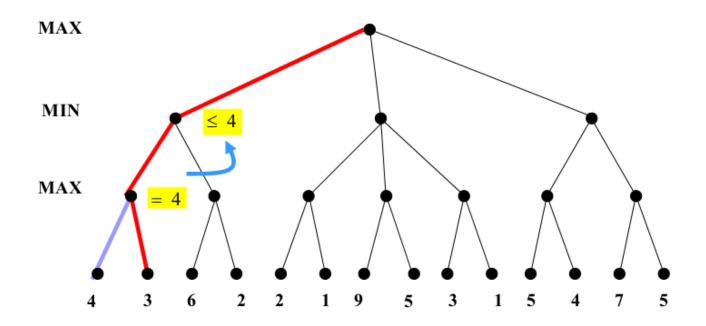

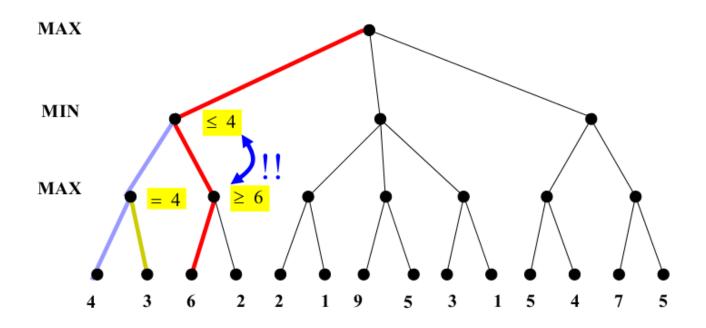

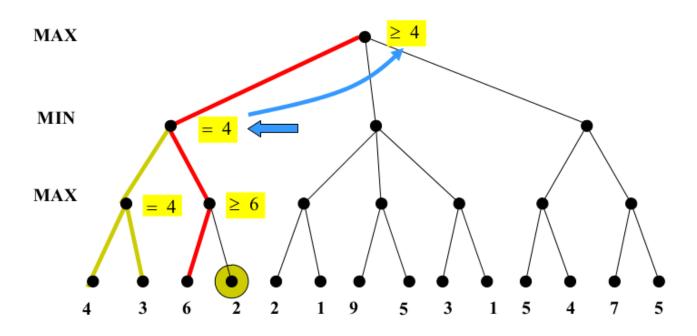

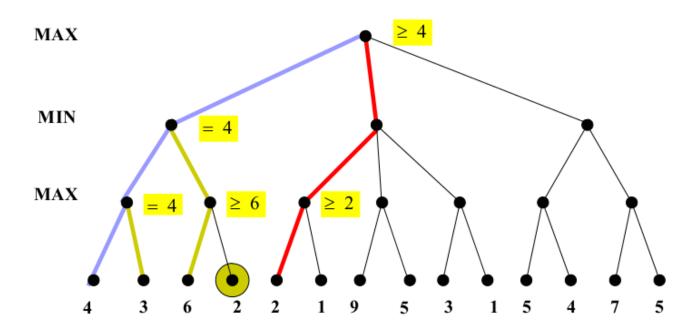

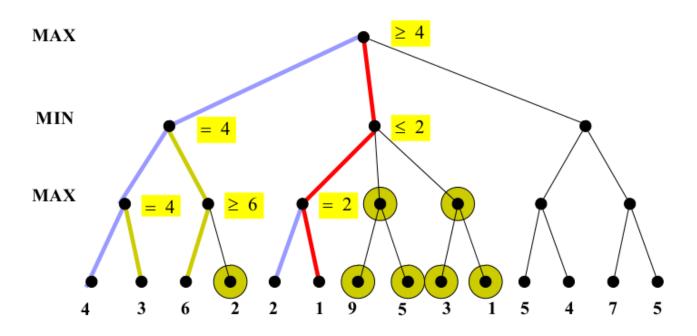

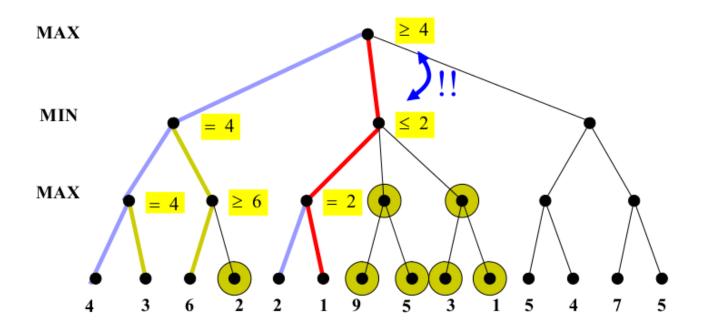

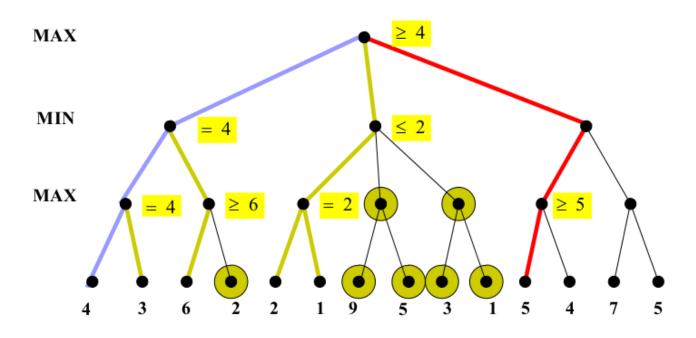

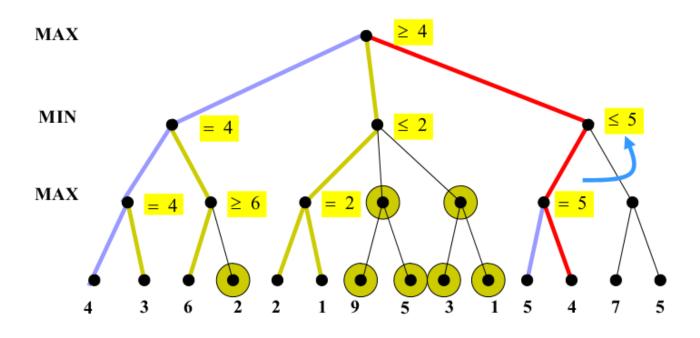

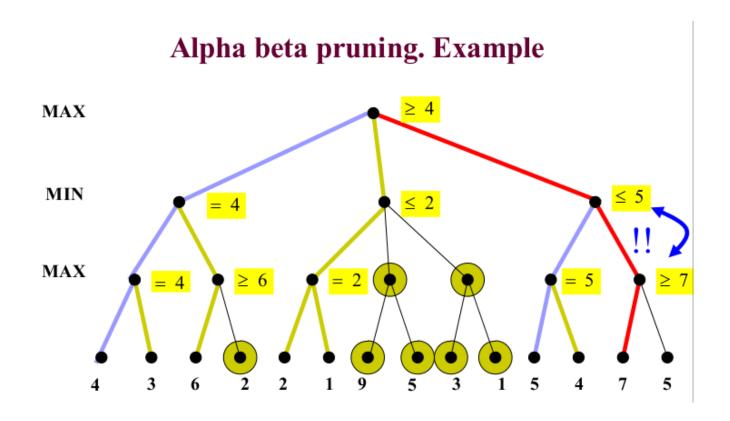

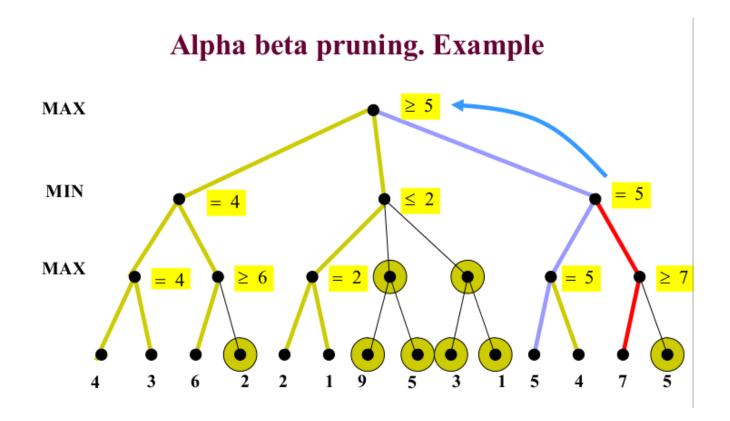

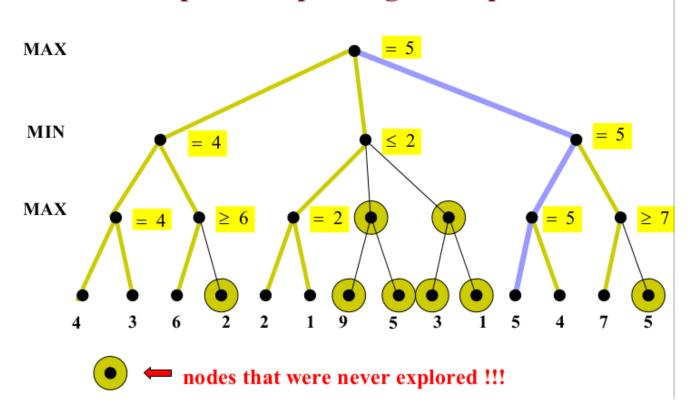

Thank You iii
